RFC 8650
Dynamic Subscription to YANG Events and Datastores over RESTCONF

Abstract
This document provides a RESTCONF binding to the dynamic subscription capability of both subscribed notifications and YANG-Push.

Status of This Memo
This is an Internet Standards Track document.
This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at https://www.rfc-editor.org/info/rfc8650.

1. Introduction

Mechanisms to support event subscription and YANG-Push are defined in [RFC8639]. Enhancements to [RFC8639] that enable YANG datastore subscription and YANG-Push are defined in [RFC8641]. This document provides a transport specification for dynamic subscriptions over RESTCONF [RFC8040]. Requirements for these mechanisms are captured in [RFC7923].

The streaming of notifications that encapsulate the resulting information push is done via the mechanism described in Section 6.3 of [RFC8040].

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

The following terms use the definitions from [RFC8639]: dynamic subscription, event stream, notification message, publisher, receiver, subscriber, and subscription.

Other terms reused include datastore, which is defined in [RFC8342], and HTTP/2 stream, which maps to the definition of "stream" within [RFC7540], Section 2.

3. Dynamic Subscriptions

This section provides specifics on how to establish and maintain dynamic subscriptions over RESTCONF [RFC8040]. Subscribing to event streams is accomplished in this way via RPCs defined within [RFC8639], Section 2.4. The RPCs are done via RESTCONF POSTs. YANG datastore subscription is accomplished via augmentations to [RFC8639] as described within [RFC8641], Section 4.4.

As described in Section 6.3 of [RFC8040], a GET needs to be performed on a specific URI on the publisher. Subscribers cannot predetermine the URI against which a subscription might exist on a publisher, as the URI will only exist after the "establish-subscription" RPC has been accepted. Therefore, the POST for the "establish-subscription" RPC replaces the GET request for the "location" leaf that is used in [RFC8040] to obtain the URI. The subscription URI will be determined and sent as part of the response to the "establish-subscription" RPC, and a
subsequent GET to this URI will be done in order to start the flow of notification messages back to the subscriber. As specified in Section 2.4.1 of [RFC8639], a subscription does not move to the active state until the GET is received.

3.1. Transport Connectivity

For a dynamic subscription, when a RESTCONF session doesn’t already exist, a new RESTCONF session is initiated from the subscriber.

As stated in Section 2.1 of [RFC8040], a subscriber MUST establish the HTTP session over TLS [RFC8446] in order to secure the content in transit.

Without the involvement of additional protocols, HTTP sessions by themselves do not support quick recognition of the loss of the communication path to the publisher. Where quick recognition of the loss of a publisher is required, a subscriber SHOULD use a TLS heartbeat [RFC6520], just from subscriber to publisher, to track HTTP session continuity.

Loss of the heartbeat MUST result in the teardown of any subscription-related TCP sessions between those endpoints. A subscriber can then attempt to re-establish the dynamic subscription by using the procedure described in Section 3.4.

3.2. Discovery

Subscribers can learn which event streams a RESTCONF server supports by querying the "streams" container of ietf-subscribed-notifications.yang in [RFC8639]. Support for the "streams" container of ietf-restconf-monitoring.yang in [RFC8040] is not required. In the case when the RESTCONF binding specified by this document is used to convey the "streams" container from ietf-restconf-monitoring.yang (i.e., that feature is supported), any event streams contained therein are also expected to be present in the "streams" container of ietf-restconf-monitoring.yang.

Subscribers can learn which datastores a RESTCONF server supports by following Section 2 of [RFC8527].

3.3. RESTCONF RPCs and HTTP Status Codes

Specific HTTP response codes as defined in Section 6 of [RFC7231] will indicate the result of RESTCONF RPC requests with the publisher. An HTTP status code of 200 is the proper response to any successful RPC defined within [RFC8639] or [RFC8641].

If a publisher fails to serve the RPC request for one of the reasons indicated in Section 2.4.6 of [RFC8639] or Appendix A of [RFC8641], this will be indicated by an appropriate error code, as shown below, transported in the HTTP response.

When an HTTP error code is returned, the RPC reply MUST include an <rpc-error> element per Section 7.1 of [RFC8040] with the following parameter values:

- an "error-type" node of "application".

---

Voit, et al. Standards Track Page 4
• an "error-tag" node whose value is a string that corresponds to an identity associated with the error. This "error-tag" will come from one of two places and will correspond to the error identities either within Section 2.4.6 of [RFC8639] for general subscription errors (Table 1) or within Appendix A.1 of [RFC8641] for subscription errors specific to YANG datastores (Table 2).

• an "error-app-tag" node whose value is a string that corresponds to an identity associated with the error, as defined in Section 2.4.6 of [RFC8639] for general subscriptions or Appendix A.1 of [RFC8641] for subscription errors specific to YANG datastores. The tag to use depends on the RPC for which the error occurred. Viable errors for different RPCs are found in Table 3.

</tbody>
</table>

*Table 2: Datastore-Specific Error Identities and Associated "error-tag" Use*
Each error identity will be inserted as the "error-app-tag" using JSON encoding following the form `<modulename>:<identityname>`. An example of such a valid encoding would be "ietf-subscribed-notifications:no-such-subscription".

In the case of error responses to an "establish-subscription" or "modify-subscription" request, there is the option to include an "error-info" node. This node may contain hints for parameter settings that might lead to successful RPC requests in the future. Tables 4 and 5 show the yang-data structures that may be returned.

<table>
<thead>
<tr>
<th>RPC</th>
<th>Select an identity with a base</th>
</tr>
</thead>
<tbody>
<tr>
<td>establish-subscription</td>
<td>establish-subscription-error</td>
</tr>
<tr>
<td>modify-subscription</td>
<td>modify-subscription-error</td>
</tr>
<tr>
<td>delete-subscription</td>
<td>delete-subscription-error</td>
</tr>
<tr>
<td>kill-subscription</td>
<td>delete-subscription-error</td>
</tr>
<tr>
<td>resync-subscription</td>
<td>resync-subscription-error</td>
</tr>
</tbody>
</table>

*Table 3: RPC Errors and Associated Error Identities*

The yang-data included within "error-info" SHOULD NOT include the optional leaf "reason", as such a leaf would be redundant with information that is already placed within the "error-app-tag".

In case of an `<rpc-error>` as a result of a "delete-subscription", a "kill-subscription", or a "resync-subscription" request, no "error-info" needs to be included, as the "subscription-id" is the only RPC input parameter, and no hints regarding this RPC input parameters need to be provided.
Note that "error-path" [RFC8040] does not need to be included with the <rpc-error> element, as subscription errors are generally associated with the choice of RPC input parameters.

3.4. Call Flow for Server-Sent Events

The call flow for Server-Sent Events (SSE) is defined in Figure 1. The logical connections denoted by (a) and (b) can be a TCP connection or an HTTP/2 stream (if HTTP/2 is used, multiple HTTP/2 streams can be carried in one TCP connection). Requests to RPCs as defined in [RFC8639] or [RFC8641] are sent on a connection indicated by (a). A successful "establish-subscription" will result in an RPC response returned with both a subscription identifier that uniquely identifies a subscription, as well as a URI that uniquely identifies the location of subscription on the publisher (b). This URI is defined via the "uri" leaf in the data model in Section 7.

An HTTP GET is then sent on a separate logical connection (b) to the URI on the publisher. This signals the publisher to initiate the flow of notification messages that are sent in SSE [W3C-20150203] as a response to the GET. There cannot be two or more simultaneous GET requests on a subscription URI: any GET request received while there is a current GET request on the same URI MUST be rejected with HTTP error code 409.

As described in Section 6.4 of [RFC8040], RESTCONF servers SHOULD NOT send the "event" or "id" fields in the SSE event notifications.
Additional requirements for dynamic subscriptions over SSE include:

- A publisher **MUST** return all subscription state notifications in a separate SSE message used by the subscription to which the state change refers.

- Subscription RPCs **MUST NOT** use the connection currently providing notification messages for that subscription.

- In addition to an RPC response for a "modify-subscription" RPC traveling over (a), a "subscription-modified" state change notification **MUST** be sent within (b). This allows the receiver to know exactly when, within the stream of events, the new terms of the subscription have been applied to the notification messages. See arrow (c).

- In addition to any required access permissions (e.g., Network Configuration Access Control Model (NACM)), the RPCs "modify-subscription", "resync-subscription", and "delete-subscription" **SHOULD** only be allowed by the same RESTCONF username [RFC8040] that invoked "establish-subscription". Such a restriction generally serves to preserve users' privacy, but exceptions might be made for administrators that may need to modify or delete other users' subscriptions.
4. QoS Treatment

QoS treatment for event streams is described in Section 2.3 of [RFC8639]. In addition, if HTTP/2 is used, the publisher MUST:

- Take the "weighting" leaf node in [RFC8639] and copy it into the HTTP/2 stream weight, Section 5.3 of [RFC7540], and
- Take any existing subscription "dependency", as specified by the "dependency" leaf node in [RFC8639], and use the HTTP/2 stream for the parent subscription as the HTTP/2 stream dependency (as described in Section 5.3.1 of [RFC7540]) of the dependent subscription.
- Set the exclusive flag (Section 5.3.1 of [RFC7540]) to 0.

For dynamic subscriptions with the same Differentiated Services Code Point (DSCP) value to a specific publisher, it is recommended that the subscriber sends all URI GET requests on a common HTTP/2 session (if HTTP/2 is used). Conversely, a subscriber cannot use a common HTTP/2 session for subscriptions with different DSCP values.

5. Notification Messages

Notification messages transported over RESTCONF will be encoded according to [RFC8040], Section 6.4.

6. YANG Tree

The YANG module defined in Section 7 has one leaf that augments three nodes of [RFC8639].

```yaml
module: ietf-restconf-subscribed-notifications
  augment /sn:establish-subscription/sn:output:
    +++-ro uri? inet:uri
  augment /sn:subscriptions/sn:subscription:
    +++-ro uri? inet:uri
  augment /sn:subscription-modified:
    +++-ro uri? inet:uri
```
7. **YANG Module**

This module references [RFC8639].
module ietf-restconf-subscribed-notifications {

8. IANA Considerations

This document registers the following namespace URI in the "ns" subregistry of the "IETF XML Registry" [RFC3688]:

Registrant Contact: The IESG.

XML: N/A; the requested URI is an XML namespace.

This document registers the following YANG module in the "YANG Module Names" registry [RFC6020]:

Name: ietf-restconf-subscribed-notifications
Prefix: rsn
Reference: RFC 8650
9. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management transports such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The Network Configuration Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

The one new data node introduced in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to this data node. These are the subtrees and data nodes and their sensitivity/vulnerability:

Container: "/subscriptions"

- "uri": leaf will show where subscribed resources might be located on a publisher. Access control must be set so that only someone with proper access permissions, i.e., the same RESTCONF [RFC8040] user credentials that invoked the corresponding "establish-subscription", has the ability to access this resource.

The subscription URI is implementation specific and is encrypted via the use of TLS. Therefore, even if an attacker succeeds in guessing the subscription URI, a RESTCONF username [RFC8040] with the required administrative permissions must be used to be able to access or modify that subscription. It is recommended that the subscription URI values not be easily predictable.

The access permission considerations for the RPCs "modify-subscription", "resync-subscription", "delete-subscription", and "kill-subscription" are described in Section 3.4.

If a buggy or compromised RESTCONF subscriber sends a number of "establish-subscription" requests, then these subscriptions accumulate and may use up system resources. In such a situation, the publisher MAY also suspend or terminate a subset of the active subscriptions from that RESTCONF subscriber in order to reclaim resources and preserve normal operation for the other subscriptions.

10. References

10.1. Normative References

[RFC3688]

[W3C-20150203]
10.2. Informative References

Appendix A. Examples

This section is non-normative. To allow easy comparison, this section mirrors the functional examples shown with NETCONF over XML within [RFC8640]. In addition, HTTP/2 vs HTTP/1.1 headers are not shown as the contents of the JSON encoded objects are identical within.

The subscription URI values used in the examples in this section are purely illustrative, and are not indicative of the expected usage that is described in Section 9.

The DSCP values are only for example purposes and are all indicated in decimal since the encoding is JSON [RFC7951].
A.1. Dynamic Subscriptions

A.1.1. Establishing Dynamic Subscriptions

The following figure shows two successful "establish-subscription" RPC requests as per [RFC8639]. The first request is given a subscription identifier of 22, and the second, an identifier of 23.

![Figure 2: Multiple Subscriptions over RESTCONF/HTTP](image)

To provide examples of the information being transported, example messages for interactions in Figure 2 are detailed below:
As the publisher was able to fully satisfy the request, the publisher sends the subscription identifier of the accepted subscription and the URI:

```
POST /restconf/operations
   /ietf-subscribed-notifications:establish-subscription

{    
   "ietf-subscribed-notifications:input": {    
      "stream-xpath-filter": "/example-module:foo/",    
      "stream": "NETCONF",    
      "dscp": 10    
   }    
}
```

*Figure 3: "establish-subscription" Request (a)*

As the publisher was able to fully satisfy the request, the publisher sends the subscription identifier of the accepted subscription and the URI:

```
HTTP status code - 200

{   
   "id": 22,   
   "uri": "https://example.com/restconf/subscriptions/22"  
}
```

*Figure 4: "establish-subscription" Success (b)*

Upon receipt of the successful response, the subscriber does a GET to the provided URI to start the flow of notification messages. When the publisher receives this, the subscription is moved to the active state (c).

```
GET /restconf/subscriptions/22
```

*Figure 5: "establish-subscription" Subsequent POST*

While not shown in *Figure 2*, if the publisher had not been able to fully satisfy the request, or the subscriber has no authorization to establish the subscription, the publisher would have sent an RPC error response. For instance, if the "dscp" value of 10 asserted by the subscriber in *Figure 3* proved unacceptable, the publisher may have returned:
A.1.2. Modifying Dynamic Subscriptions

An existing subscription may be modified. The following exchange shows a negotiation of such a modification via several exchanges between a subscriber and a publisher. This negotiation consists of a failed RPC modification request/response followed by a successful one.

If the subscription being modified in Figure 7 is a datastore subscription as per [RFC8641], the modification request made in (d) may look like that shown in Figure 8. As can be seen, the modifications being attempted are the application of a new XML Path Language (XPath) filter as well as the setting of a new periodic time interval.
POST /restconf/operations
   /ietf-subscribed-notifications:modify-subscription

{
   "ietf-subscribed-notifications:input": {
      "id": 23,
      "ietf-yang-push:datastore-xpath-filter":
         "/example-module:foo/example-module:bar",
      "ietf-yang-push:periodic": {
         "ietf-yang-push:period": 500
      }
   }
}

Figure 8: Subscription Modification Request (c)

If the publisher can satisfy both changes, the publisher sends a positive result for the RPC. If the publisher cannot satisfy either of the proposed changes, the publisher sends an RPC error response (e). The following is an example RPC error response for (e) that includes a hint. This hint is an alternative time period value that might have resulted in a successful modification:

HTTP status code - 400

{ "ietf-restconf:errors" : {
   "error" : [
      "error-type": "application",
      "error-tag": "invalid-value",
      "error-severity": "error",
      "error-app-tag": "ietf-yang-push:period-unsupported",
      "error-info": {
         "ietf-yang-push":
            "modify-subscription-datastore-error-info": {
               "period-hint": 3000
            }
      }
   ]
}

Figure 9: "modify-subscription" Failure with Hint (e)

A.1.3. Deleting Dynamic Subscriptions

The following demonstrates deleting a subscription. This subscription may have been to either a stream or a datastore.
If the publisher can satisfy the request, the publisher replies with success to the RPC request.

If the publisher cannot satisfy the request, the publisher sends an `<rpc-error>` element indicating the modification didn't work. Figure 11 shows a valid response for an existing valid subscription identifier, but that subscription identifier was created on a different transport session:

```
POST /restconf/operations
   /ietf-subscribed-notifications:delete-subscription

{  
   "delete-subscription": {  
      "id": "22"  
   }  
}
```

*Figure 10: "delete-subscription" Request*

HTTP status code - 404

```
{  
   "ietf-restconf:errors": {
      "error": [
         "error-type": "application",
         "error-tag": "invalid-value",
         "error-severity": "error",
         "error-app-tag":
            "ietf-subscribed-notifications:no-such-subscription"
      ]
   }
}
```

*Figure 11: Unsuccessful "delete-subscription"*

## A.2. Subscription State Notifications

A publisher will send subscription state notifications according to the definitions within [RFC8639].

### A.2.1. "subscription-modified"

A "subscription-modified" encoded in JSON would look like:
A.2.2. "subscription-completed", "subscription-resumed", and "replay-completed"

A "subscription-completed" notification would look like:

```
{
   "ietf-restconf:notification" : {
      "eventTime": "2007-09-01T10:00:00Z",
      "ietf-subscribed-notifications:subscription-completed": { 
         "id": 39,
      }
   }
}
```

Figure 13: "subscription-completed" Notification in JSON

The "subscription-resumed" and "replay-complete" are virtually identical, with "subscription-completed" simply being replaced by "subscription-resumed" and "replay-complete".

A.2.3. "subscription-terminated" and "subscription-suspended"

A "subscription-terminated" would look like:

```
{
   "ietf-restconf:notification" : {
      "eventTime": "2007-09-01T10:00:00Z",
      "ietf-subscribed-notifications:subscription-terminated": { 
         "id": 39,
         "error-id": "suspension-timeout"
      }
   }
}
```

Figure 14: "subscription-terminated" Subscription State Notification
The "subscription-suspended" is virtually identical, with "subscription-terminated" simply being replaced by "subscription-suspended".

A.3. Filter Example

This section provides an example that illustrates the method of filtering event record contents. The example is based on the YANG notification "vrrp-protocol-error-event" as defined per the ietf-vrrp.yang module within [RFC8347]. Event records based on this specification that are generated by the publisher might appear as:

```
data: {
data:   "ietf-restconf:notification" : {
data:     "eventTime" : "2018-09-14T08:22:33.44Z",
data:     "ietf-vrrp:vrrp-protocol-error-event" : {
data:       "protocol-error-reason" : "checksum-error"
data:     }
data:   }
data: }
```

*Figure 15: RFC 8347 (VRRP) - Example Notification*

Suppose a subscriber wanted to establish a subscription that only passes instances of event records where there is a "checksum-error" as part of a Virtual Router Redundancy Protocol (VRRP) protocol event. Also assume the publisher places such event records into the NETCONF stream. To get a continuous series of matching event records, the subscriber might request the application of an XPath filter against the NETCONF stream. An "establish-subscription" RPC to meet this objective might be:

```
POST /restconf/operations
   /ietf-subscribed-notifications:establish-subscription
{
   "ietf-subscribed-notifications:input": {
   "stream": "NETCONF",
   "stream-xpath-filter":
   "/ietf-vrrp:vrrp-protocol-error-event[protocol-error-reason='checksum-error']/",
   }
}
```

*Figure 16: Establishing a Subscription Error Reason via XPath*

For more examples of XPath filters, see [XPATH].

Suppose the "establish-subscription" in Figure 16 was accepted. And suppose later a subscriber decided they wanted to broaden this subscription cover to all VRRP protocol events (i.e., not just those with a "checksum error"). The subscriber might attempt to modify the subscription in a way that replaces the XPath filter with a subtree filter that sends all VRRP protocol events to a subscriber. Such a "modify-subscription" RPC might look like:
For more examples of subtree filters, see [RFC6241], Section 6.4.

Acknowledgments

We wish to acknowledge the helpful contributions, comments, and suggestions that were received from Ambika Prasad Tripathy, Alberto Gonzalez Prieto, Susan Hares, Tim Jenkins, Balazs Lengyel, Kent Watsen, Michael Scharf, Guangying Zheng, Martin Bjorklund, Qin Wu, and Robert Wilton.
