Abstract

This document defines a YANG data model that can be used to configure and manage Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) devices.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at https://www.rfc-editor.org/info/rfc8652.

1. Introduction

YANG [RFC6020] [RFC7950] is a data definition language that was introduced to model the configuration and running state of a device managed using network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. YANG is now also being used as a component of wider management interfaces, such as command-line interfaces (CLIs).

This document defines a YANG data model that can be used to configure and manage Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) devices. The protocol versions include IGMPv1 [RFC1112], IGMPv2 [RFC2236], IGMPv3 [RFC3376], MLDv1 [RFC2710], and MLDv2 [RFC3810]. The core features of the IGMP and MLD protocols are defined as required. Non-core features are defined as optional in the provided data model.

The YANG data model in this document conforms to the Network Management Datastore Architecture (NMDA) [RFC8342].

1.1. Terminology

The terminology for describing YANG data models is found in [RFC6020] and [RFC7950], including:

- augment
- data model
- data node
- identity
- module

The following abbreviations are used in this document and the defined model:

IGMP: Internet Group Management Protocol [RFC3376].

MLD: Multicast Listener Discovery [RFC3810].

SSM: Source-Specific Multicast service model [RFC3569] [RFC4607].
1.2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.3. Tree Diagrams

Tree diagrams used in this document follow the notation defined in [RFC8340].

1.4. Prefixes in Data Node Names

In this document, names of data nodes, actions, and other data model objects are often used without a prefix, as long as it is clear from the context in which YANG module each name is defined. Otherwise, names are prefixed using the standard prefix associated with the corresponding YANG module, as shown in Table 1.

Table 1: Prefixes and Corresponding YANG Modules
2. Design of the Data Model

2.1. Scope of Model

The model covers IGMPv1 [RFC1112], IGMPv2 [RFC2236], IGMPv3 [RFC3376], MLDv1 [RFC2710], and MLDv2 [RFC3810].

This model does not cover other IGMP- and MLD-related protocols such as IGMP/MLD Proxy [RFC4605] or IGMP/MLD Snooping [RFC4541] etc., which will be specified in separate documents.

This model can be used to configure and manage various versions of IGMP and MLD protocols. The operational state data and statistics can be retrieved by this model. Even though no protocol-specific notifications are defined in this model, the subscription and push mechanism defined in [RFC8639] and [RFC8641] can be implemented by the user to subscribe to notifications on the data nodes in this model.

The model contains all the basic configuration parameters to operate the protocols listed above. Depending on the implementation choices, some systems may not allow some of the advanced parameters to be configurable. The occasionally implemented parameters are modeled as optional features in this model, while the rarely implemented parameters are not included this model and left for augmentation. This model can be extended, and it has been structured in a way that such extensions can be conveniently made.

The protocol parameters covered in this model can been seen from the model structure described in Section 3.

The protocol parameters that were considered but are not covered in this model are described in the following sections.

2.1.1. Parameters Not Covered at the Global Level

The configuration parameters and operational states not covered on an IGMP instance or an MLD instance are:

- Explicit tracking
- Maximum transmit rate
- Last member query count
• Other querier present time
• Send router alert
• Startup query interval
• Startup query count

2.1.2. Parameters Not Covered at the Interface Level

The configuration parameters and operational states not covered on an IGMP interface or an MLD interface are:

• Disable router alert check
• Drop IGMP version 1, IGMP version 2, or MLD version 1
• Last member query count
• Maximum number of sources
• Other querier present time
• Passive mode
• Promiscuous mode
• Query before immediate leave
• Send router alert

2.2. Optional Capabilities

This model is designed to represent the capabilities of IGMP and MLD devices with various specifications, including the basic capability subsets of the IGMP and MLD protocols. The main design goals of this document are that the basic capabilities described in the model are supported by any major now-existing implementation, and that the configuration of all implementations meeting the specifications is easy to express through some combination of the optional features in the model and simple vendor augmentations.

There is also value in widely supported features being standardized, to provide a standardized way to access these features, to save work for individual vendors, and so that mapping between different vendors’ configuration is not needlessly complicated. Therefore, this model declares a number of features representing capabilities that not all deployed devices support.

The extensive use of feature declarations should also substantially simplify the capability negotiation process for a vendor’s IGMP and MLD implementations.
On the other hand, operational state parameters are not so widely designated as features, as there are many cases where the defaulting of an operational state parameter would not cause any harm to the system, and it is much more likely that an implementation without native support for a piece of operational state would be able to derive a suitable value for a state variable that is not natively supported.

2.3. Position of Address Family in Hierarchy

The protocol IGMP only supports IPv4, while the protocol MLD only supports IPv6. The data model defined in this document can be used for both IPv4 and IPv6 address families.

This document defines IGMP and MLD as separate schema branches in the structure. The benefits are:

- The model can support IGMP (IPv4), MLD (IPv6), or both optionally and independently. Such flexibility cannot be achieved cleanly with a combined branch.
- The structure is consistent with other YANG data models such as RFC 8344, which uses separate branches for IPv4 and IPv6.
- The separate branches for IGMP and MLD can accommodate their differences better and cleaner. The two branches can better support different features and node types.

3. Module Structure

This model augments the core routing data model specified in [RFC8349].
The "igmp" container instantiates an IGMP protocol of version IGMPv1, IGMPv2, or IGMPv3. The "mld" container instantiates an MLD protocol of version MLDv1 or MLDv2.

The YANG data model defined in this document conforms to the Network Management Datastore Architecture (NMDA) [RFC8342]. The operational state data is combined with the associated configuration data in the same hierarchy [RFC8407].

A configuration data node is marked as mandatory only when its value must be provided by the user. Where nodes are not essential to protocol operation, they are marked as optional. Some other nodes are essential but have a default specified, so that they are also optional and need not be configured explicitly.

3.1. IGMP Configuration and Operational State

The IGMP data is modeled as a schema subtree augmenting the "control-plane-protocol" data node under "/rt:routing/rt:control-plane-protocols" in the module ietf-routing, following the convention described in [RFC8349]. The augmentation to the module ietf-routing allows this model to support multiple instances of IGMP, but a restriction MAY be added depending on the implementation and the device. The identity "igmp" is derived from the "rt:control-plane-protocol" base identity and indicates that a control-plane-protocol instance is IGMP.

The IGMP subtree is a three-level hierarchy structure as listed below:

Global level: Including IGMP configuration and operational state attributes for the entire IGMP protocol instance in this router.

Interface-global level: Including configuration data nodes that are applicable to all the interfaces whose corresponding nodes are not defined or not configured at the interface level. For such a node at the interface level, the system uses the same value of the corresponding node at the interface-global level.

Interface level: Including IGMP configuration and operational state attributes specific to the given interface. For a configuration node at the interface level, there may exist a corresponding configuration node with the same name at the interface-global level. The value configured on a node at the interface level overrides the value configured on the corresponding node at the interface-global level.

3.2. **MLD Configuration and Operational State**

The MLD data is modeled as a schema subtree augmenting the "control-plane-protocol" data node under "/rt:routing/rt:control-plane-protocols" in the module ietf-routing, following the convention described in [RFC8349]. The augmentation to the module ietf-routing allows this model to support multiple instances of MLD, but a restriction **MAY** be added depending on the implementation and the device. The identity "mld" is derived from the "rt:control-plane-protocol" base identity and indicates that a control-plane-protocol instance is MLD.

The MLD subtree is a three-level hierarchy structure as listed below:

- **Global level:** Including MLD configuration and operational state attributes for the entire MLD protocol instance in this router.

- **Interface-global level:** Including configuration data nodes that are applicable to all the interfaces whose corresponding nodes are not defined or not configured at the interface level. For such a node at the interface level, the system uses the same value of the corresponding node at the interface-global level.

- **Interface level:** Including MLD configuration and operational state attributes specific to the given interface. For a configuration node at the interface level, there may exist a corresponding configuration node with the same name at the interface-global level. The value configured on a node at the interface level overrides the value configured on the corresponding node at the interface-global level.

        |  {intf-immediate-leave}?
        +--rw max-groups? uint32
3.3. IGMP and MLD Actions

IGMP and MLD each have one action that clears the group membership cache entries for that protocol.
4. IGMP and MLD YANG Module

5. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The Network Configuration Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:
igmp-mld:global
This subtree specifies the configuration for the IGMP attributes at the global level on an IGMP instance. Modifying the configuration can cause IGMP membership to be deleted or reconstructed on all the interfaces of an IGMP instance.

igmp-mld:interfaces
This subtree specifies the configuration for the IGMP attributes at the interface-global level on an IGMP instance. Modifying the configuration can cause IGMP membership to be deleted or reconstructed on all the interfaces of an IGMP instance.

igmp-mld:interfaces/interface
This subtree specifies the configuration for the IGMP attributes at the interface level on an IGMP instance. Modifying the configuration can cause IGMP membership to be deleted or reconstructed on a specific interface of an IGMP instance.

Under /rt:routing/rt:control-plane-protocols
/rt:control-plane-protocol/igmp-mld:igmp,

igmp-mld:global
This subtree specifies the configuration for the MLD attributes at the global level on an MLD instance. Modifying the configuration can cause MLD membership to be deleted or reconstructed on all the interfaces of an MLD instance.

igmp-mld:interfaces
This subtree specifies the configuration for the MLD attributes at the interface-global level on an MLD instance. Modifying the configuration can cause MLD membership to be deleted or reconstructed on all the interfaces of an MLD instance.
This subtree specifies the configuration for the MLD attributes at the interface level on a device. Modifying the configuration can cause MLD membership to be deleted or reconstructed on a specific interface of an MLD instance.

Unauthorized access to any data node of these subtrees can adversely affect the membership records of multicast routing subsystem on the local device. This may lead to network malfunctions, delivery of packets to inappropriate destinations, and other problems.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

```
/rt:routing/rt:control-plane-protocols
/rt:control-plane-protocol/igmmp-mld:igmp
/rt:routing/rt:control-plane-protocols
/rt:control-plane-protocol/igmp-mld:mld
```

Unauthorized access to any data node of the above subtree can disclose the operational state information of IGMP or MLD on this device.

Some of the action operations in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. These are the operations and their sensitivity/vulnerability:

```
/rt:routing/rt:control-plane-protocols
/rt:control-plane-protocol/igmmp-mld:igmp/igmmp-mld:clear-groups
/rt:routing/rt:control-plane-protocols
/rt:control-plane-protocol/igmp-mld:mld/igmp-mld:clear-groups
```

Unauthorized access to any of the above action operations can delete the IGMP or MLD membership records on this device.

### 6. IANA Considerations

This document registers the following namespace URIs in the IETF XML registry [RFC3688]:
This document registers the following YANG modules in the YANG Module Names registry [RFC6020]:

- Name: ietf-igmp-mld
- Prefix: igmp-mld
- Reference: RFC 8652
